

# Innovative Formulations for Solid and Hybrid Rocket Propulsion

**Luigi T. DeLuca**

Professor (RET)

SPLab - Space Propulsion Laboratory

DAST - Department of Aerospace Science and Technology

PoliMi - Politecnico di Milano, I-20156 Milan, Mi, Italy

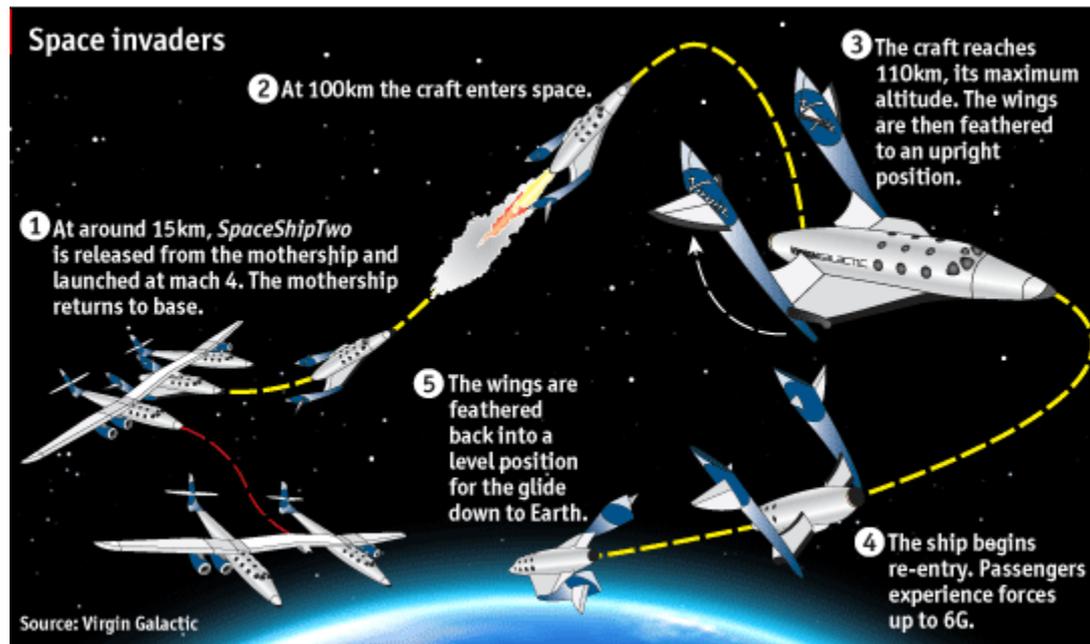

# Plan of Presentation - Overall

## → General Introduction to Rocket Propulsion

- Basic Concepts and Definitions
- Solid Rocket Motors (SRM)
- Solid Rocket Propellants (SRP)
- Metallized Formulations
- Nanosized Metals
- Solid Fuels for Hybrid Propulsion
- Conclusions and Future Developments

# Introduction Propulsion 1

- **Propulsion** is the applied science that studies and designs those devices, called engines/motors/thrusters, capable to modify the motion of a body (for example, start a motion, change velocity and/or direction, stop a motion in progress).
- In a broad sense, propulsion also studies the associated operating modes (such as trajectory optimization).
- **Aerospace propulsion** specifically studies and implements applications for both the aeronautical domain (that is, with altitudes limited by the presence of an atmosphere) and the space domain (that is, in vacuum).
- **Conventionally**, 100 km altitude is the accepted boundary aero/space.

# Introduction Propulsion 2

- **Jet propulsion** is a particular but widespread propulsion technique based on the principle of momentum conservation: expulsion of matter in a given direction (action) causes a thrust (reaction) in the same direction but opposite sign.
- **Propellant** (or expellant) is the matter that constitutes the exhaust jet.
- While the exhaust jet is mainly or totally in the **gaseous** state (gasdynamic nozzles suffer in the presence of condensed phase), the propellant stored in the tank(s) is commonly in the **liquid or solid** state (to save volume and inert mass, as for all flying objects).
- According to the specific propulsive device, the exhaust jet - in addition to mass - involves a variety of further **effects**: thermal (high or low temperature), chemical (reactive or inert), electrical (charged or neutral), visibility, pollution, radioactivity, and so on.

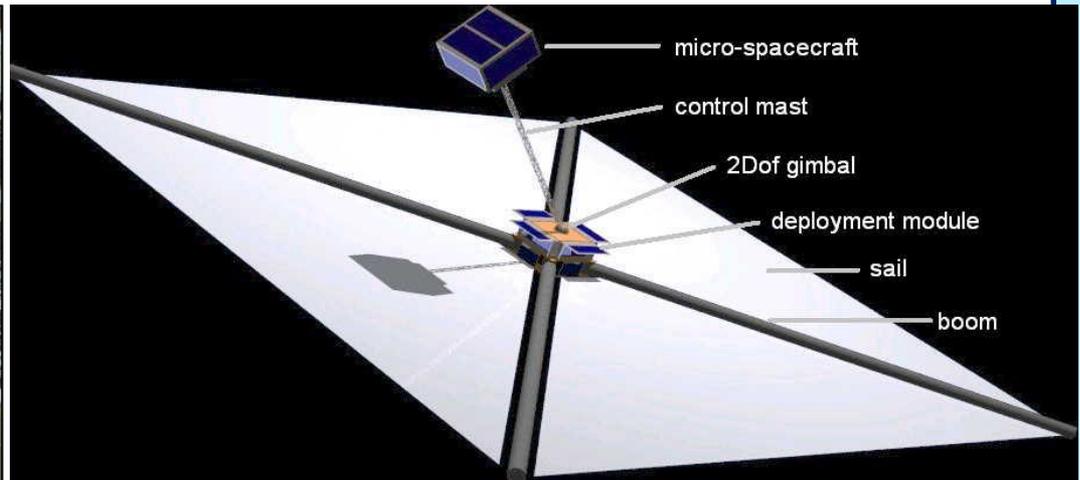

# Introduction Propulsion 3a

- **Propellantless** propulsion is of particular interest **for space navigation** (specific impulse more important than thrust); for example: solar sails.
- **Solar sails** offer a wide range of applications for high-energy low-cost missions in space propulsion with low-thrust and no propellant. Sails are accelerated in space by reflecting solar photons off large mirroring surfaces, thereby transforming the momentum of photons into a propulsive force.

Fully deployed 20 m × 20 m solar sail at DLR-Cologne

DLR design for a free-flying three-axis stabilized sailcraft with deployed control mast

# Introduction 4

- Propulsion in general is **not** a basic science, but resorts to concepts and notions of chemistry, thermodynamics, heat transfer, radiation, mechanics, gasdynamics, electromagnetism, and possibly nuclear physics.
- Difficulties that are faced in the theoretical studies and practical realizations are due to the needed **integration** of very different topics and the **extreme** values of operating conditions:
  - **pressures** ranging from vacuum up to  $o(100)$  di atm
  - **temperatures** from  $o(10)$  K up to  $o(10,000)$  K
  - operation **times** variable from fractions of second to weeks (even years, in the case of satellites or interplanetary probes)
  - **gasdynamics** from subsonic to supersonic and maybe hypersonic
  - multiphase reactive turbulent compressible **flows**
  - **cryogenic** hydraulics,
  - intense **heat transfer** also of radiant nature
  - and so on.

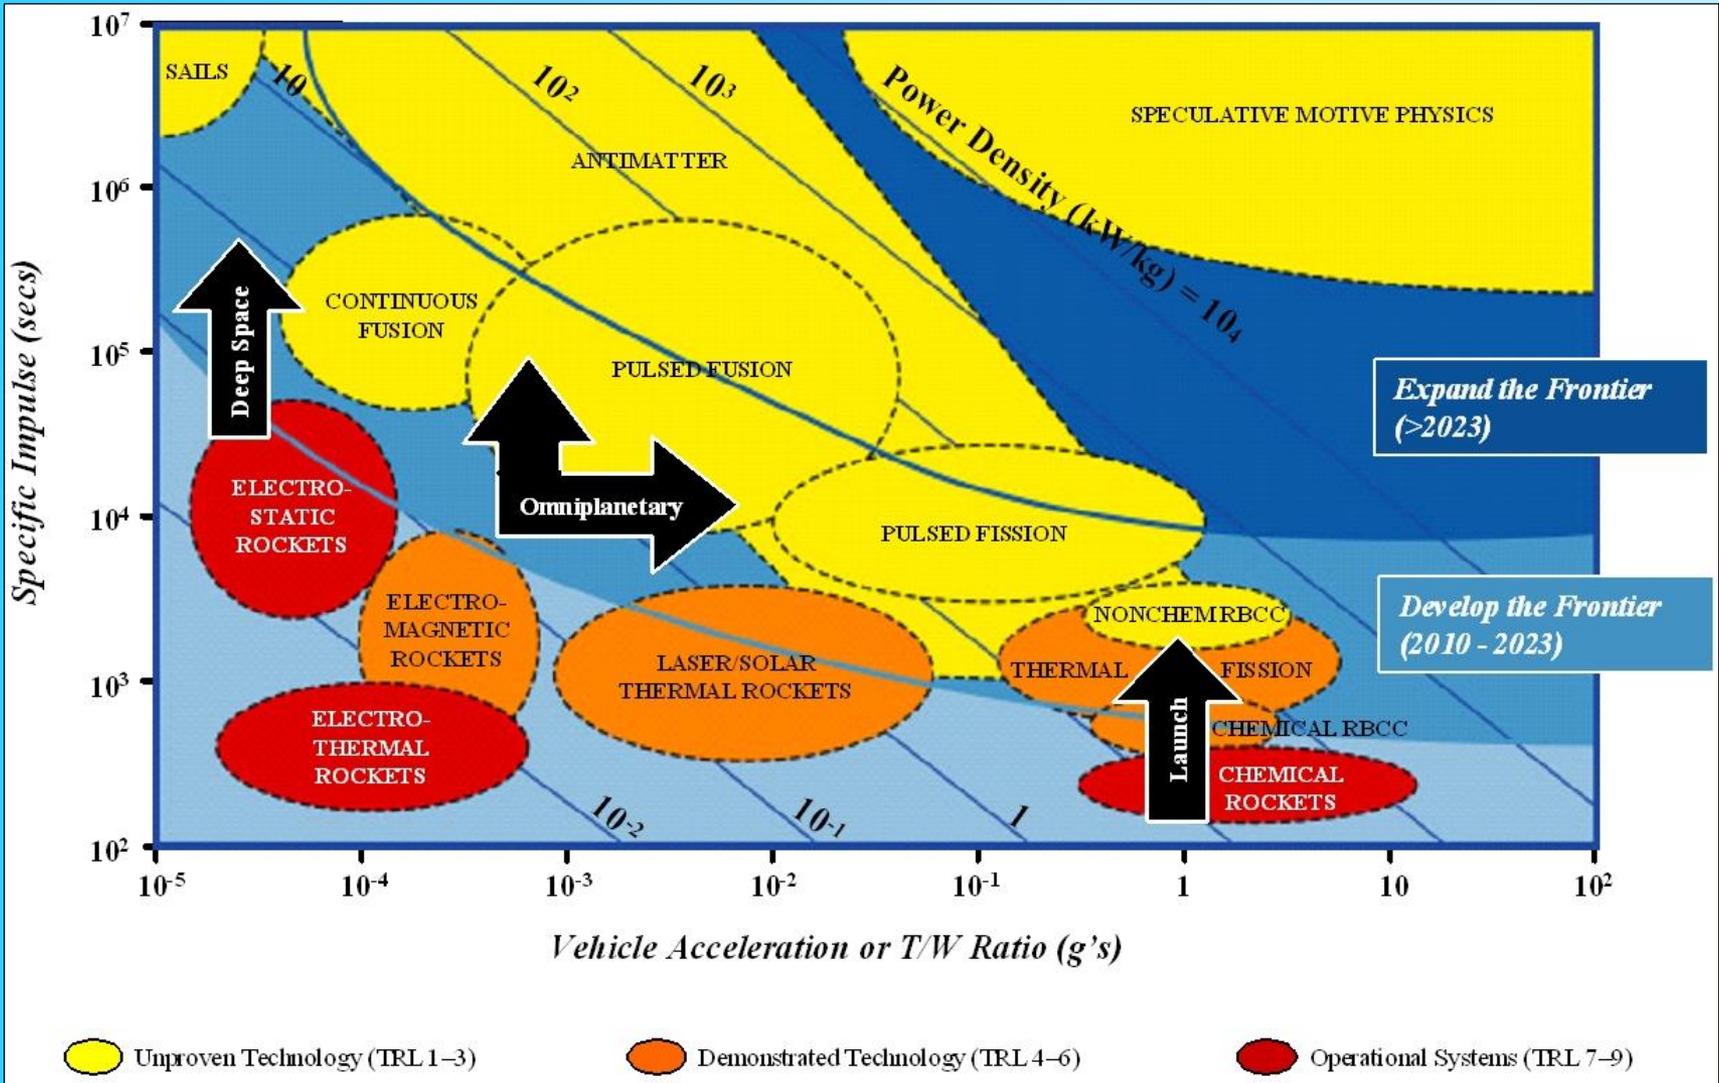

# Plan of Presentation - Overall

# NASA State of the Art for Space Exploration

TRL = Technology Readiness Level

DeLuca 8

# The European Space Launchers Family

Ariane-5 up 4,000 - 19,500 kg

Soyuz 1,500 - 4,900 kg

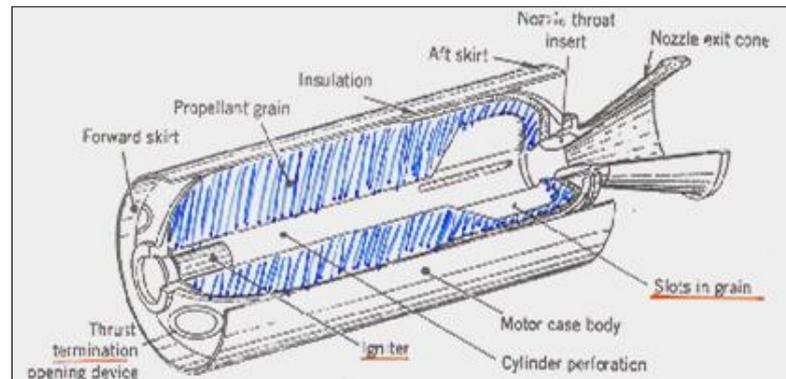

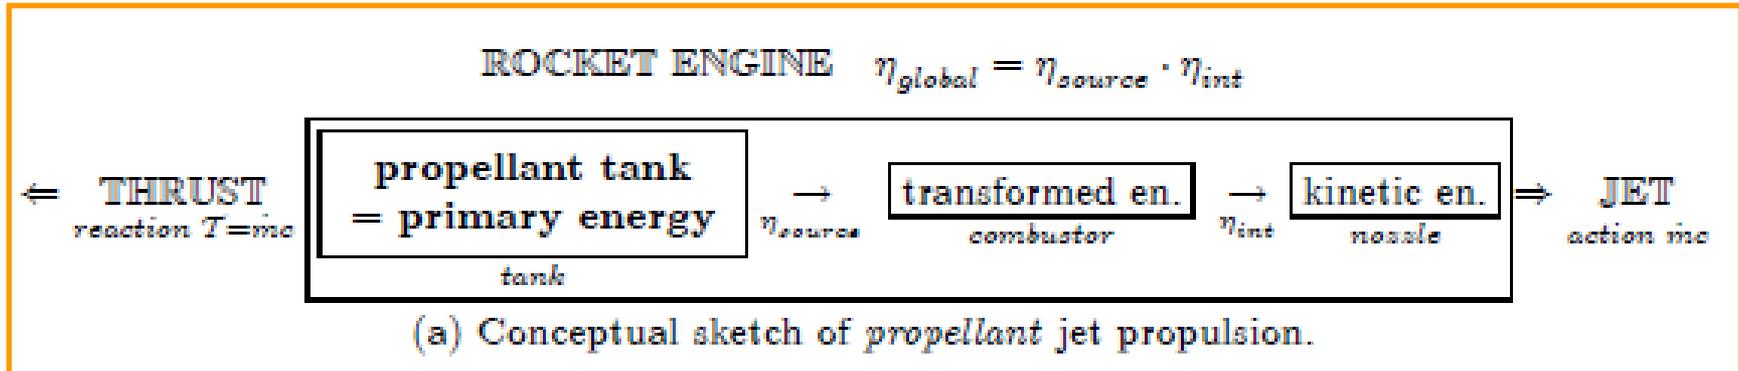

Vega 50 - 1,500 (2,500 next) kg

# Energetics 1a

- From an energetic viewpoint, all **jet engines** (whether of rocket or airbreathing kind) can conceptually be portrayed as indicated in the following sketch.
- A typical, but not exclusive, configuration for thermochemical propulsion includes a **propellant/energy tank**, propellant combustor/energy **converter**, propellant **accelerator**.

# SOLID ROCKET PROPULSION

DeLuca 11

30 Apr 2014 01h 35min UT

## ADVANTAGES:

- High Thrust Density
- Readiness/Storability
- Manufacturing
- Cost
- **High TRL**

## DISADVANTAGES:

- Short firing time
- No ON/OFF capability
- **Modest  $I_s$**

# HYBRID ROCKET PROPULSION

## ADVANTAGES:

- Low Cost
- Safety and Low Impact
- ON/OFF and Throttling
- **Possible High  $I_s$**

## DISADVANTAGES:

- Low Regression Rate
- Poor Combustion Efficiency
- Time-varying Performance (?)
- **Low TRL**

FLOX/HTPB + Li with 11 perforations fuel grain showed  $I_s = 380$  s for  $\epsilon = 40$ .

# Main Features SP vs. HP

- Solid propulsion SP is a **mature** technology much used for a variety of civil and military applications.
  - ***SRM provide prompt and storable large thrust in a compact, simple, reliable, and low-cost unit. High TRL.***
  
- Hybrid Propulsion HP is a **promising** technology in principle useful for a variety of civil and military applications.
  - ***HRE may provide large thrust featuring low-cost and a good operation flexibility. Low TRL.***
  
- Thanks to some specific features (large thrust density, use readiness, long time storability, simplicity of operations ...), SP will still be **used** for decades, especially for military missions.
- Follow Up: a wide body of literature available, but sensitive data not public.
- Purpose: offer a general **survey** of the current status and point out innovative solid or hybrid rocket formulations.

# State-of-the-Art

Current state of the art in chemical rocket propulsion.

## **Chemical Rocket Propulsion**

A Comprehensive Survey of Energetic Materials

Series: Springer Aerospace Technology

- ▶ Brings together topics that are currently scattered across the literature, saving the reader time
- ▶ Presents research from across the world, including from Russian and Chinese teams whose work is not usually available
- ▶ Gives new research results in chemical propulsion

Developed and expanded from the work presented at the New Energetic Materials and Propulsion Techniques for Space Exploration workshop in June 2014, this book contains new scientific results, up-to-date reviews, and inspiring perspectives in a number of areas related to the energetic aspects of chemical rocket propulsion. This collection covers the entire life of energetic materials from their conceptual formulation to practical manufacturing; it includes coverage of theoretical and experimental ballistics, performance properties, as well as laboratory-scale and full system-scale, handling, hazards, environment, ageing, and disposal.

Chemical Rocket Propulsion is a unique work, where a selection of accomplished experts from the pioneering era of space propulsion and current technologists from the most advanced international laboratories discuss the future of chemical rocket propulsion for access to, and exploration of, space. It will be of interest to both postgraduate and final-year undergraduate students in aerospace engineering, and practicing aeronautical engineers and designers, especially those with an interest in propulsion, as well as researchers in energetic materials.

## Once Upon A Time In China

DeLuca 21

*Solid rocket propulsion fortuitously stems from alchemist activities in China dating as early as 220 BC ca. Drugs made from minerals and metallic substances were considered more effective than the herbal ones. Black powder, or something similar, was a mixture of saltpeter ( $KNO_3$ ), sulfur and charcoal - in various proportions - initially studied for medical reasons (elixir, longevity, immortality). The search for elixirs of immortality failed (being actually poisonous), but a new weapon was instead discovered.*

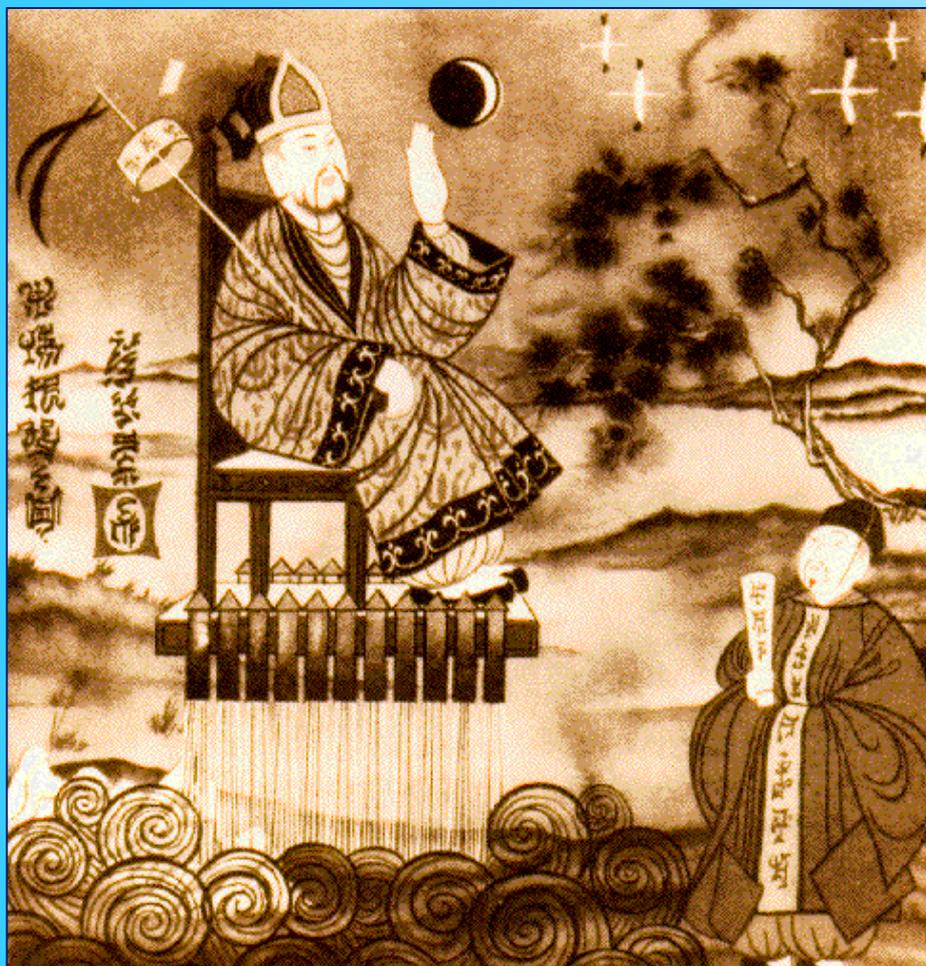

Chinese soldier launches fire-arrow

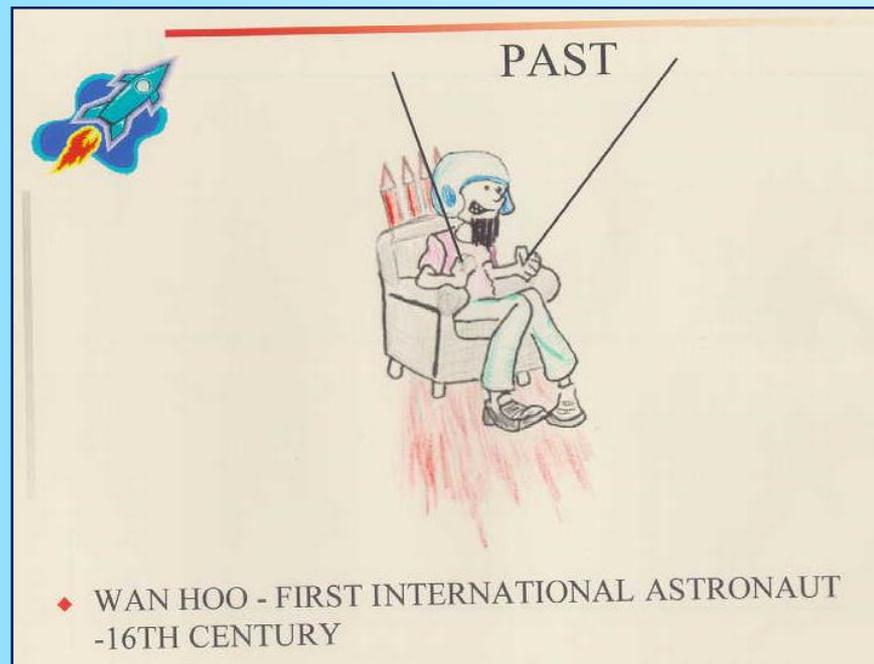

# Once Upon A Time In China...

*Wan Hoo or Wan Pu, circa 1500, a legendary mandarin  
47 rockets (KNO<sub>3</sub>+S+charcoal in bamboo canes)*

DeLuca 22

Wàn Hǔ (萬虎 or 萬戶) (d. ca. 1500) was a minor Chinese official of the Ming dynasty who attempted to become the world's first recorded astronaut. The crater Wan-Hoo on the far side of the Moon is named after him.

13. Hybrid propellant hopes - HRE
14. Actual motor performance – SRM & HRE

# Future 1

Several families of HEDM propellants were identified, such as formulations based on high-nitrogen compounds, octanitrocubane  $C_8(NO_2)_8$ , metallic hydrogen, atomic radicals, metastable helium, and so on.

**Metallic hydrogen** is a theoretically dense energetic material (not yet produced on earth). The TRL level is not at level 1 as the characteristics are based on theoretical calculations. The estimated density at ambient conditions is  $7 \text{ g/cm}^3$ , 10 times LH2. Above a critical temperature, possibly 1000 K, metallic hydrogen will become unstable and recombine to the molecular phase, releasing the energy of recombination, 216 MJ/kg (for reference: LH2/LOx in the SSME releases 10 MJ/kg, RP1/LOx releases 6 MJ/kg). Ongoing experiments are using diamond anvil cells and short pulse laser technologies to follow the hydrogen melt line toward the conditions for the metallic state. Expected  $I_s$  values are in the 500-2000 s range.

The challenges in implementing are: upgrading existing experimental equipment is required for synthesis and characterization of small quantities of metallic hydrogen. Also, scaling up production by many orders of magnitude is required. Engine components must be developed that are compatible with metallic hydrogen. Test engines must be developed to verify expected operations and performance with a variety of diluents and mixture ratios. Potentially, there is a need for tankage that operates at several thousands MPa of pressure.

# Future 2

**High-energy oxidizers** such as **fluorinated compounds** include fluorides such as ClF<sub>3</sub>, ClF<sub>5</sub>, and OF<sub>2</sub>. These oxidizers were tested in the 1980s under the Strategic Defense Initiative (SDI). Flight testing was planned for hydrazine/ClF<sub>5</sub>.

**Atomic Boron /Carbon /Hydrogen** propellant have been investigated for many decades. Atomic hydrogen, boron, and carbon fuels are very high energy density, **free-radical propellants**. These atoms have been trapped in solid cryogenics (neon, etc.) at 0.2 to 2 mass %. **Atomic hydrogen may deliver an  $I_s \approx 600$  to 1,500 s**. There has been great progress in the improvement of atom storage density over the last several decades. Laboratory studies have demonstrated 0.2 and 2 mass % atomic hydrogen in a solid hydrogen matrix. If the atom storage were to reach 10–15 mass %, which would produce  $I_s \approx 600 - 750$  s. The storage of atoms at 10, 15, or 50 mass % is needed for effective propulsion.

**High-nitrogen compounds** (N<sub>4</sub>, N<sub>5+</sub>, N<sub>5-</sub>, N<sub>8</sub>, etc.) are potentially the **most powerful** chemical explosives created in history. Work was conducted on N<sub>5+</sub> and N<sub>5-</sub> in USA (AFOSR HEDM Program) and Sweden (N<sub>5-</sub>). Gram quantities of the (N<sub>5+</sub>) ionic salt were produced in the laboratory. Theoretical studies have shown that these materials **may have in-space** propulsion applications.

DeLuca 28

# Future 3

Most of the previous HEDM are still **far from being practically usable in the short range** due to severe difficulties in large scale manufacture, ground processing, personnel safety, handling safety, transportation, prolonged storage, and cost considerations. In particular, these materials are highly shock sensitive.

Presently, there are **no integrated vehicle designs** that can make use of these possible propellants.

Work is continuing worldwide.

# SOLID ROCKET PROPULSION

## How to Improve Performance ?

### Typical Performance Losses SRM (10% of ideal vacuum $I_s \approx 330$ s)

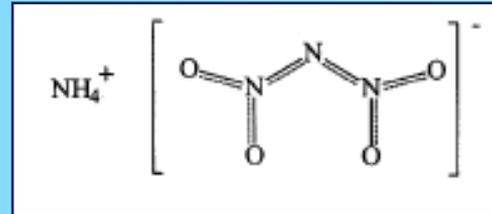

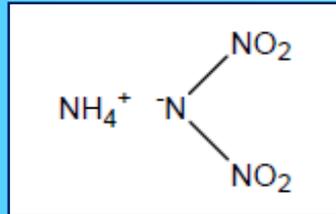

- Two phase flow losses (2P, 35% of overall losses, say about 10-13 s)
- Combustion losses (5% of overall losses, say  $\leq 5$  s)

### Two approaches can be taken

- **Evolutionary** (for about 50 years, after AI and HTPB): mitigate performance losses, mainly **2P losses**, of current (existing) propulsion systems. But little room left..., Green Programs for Clean Space...
- **Revolutionary long range**: Many new compounds proposed, but they are far from being practically usable in the short range due to a variety of **severe difficulties** in large scale manufacture, ground processing, personnel safety at different stages, handling and transportation safety, shock sensitivity, prolonged storage, and cost considerations. Work is continuing every day, but presently **no integrated vehicle designs make use** of these radically new potential propellant ingredients or formulations
- **Revolutionary feasible now**: use **viable innovative** energetic ingredients or techniques to augment performance and mitigate impact of rocket propulsion systems (Pak, 1993).

Approach according to Pak [Ref. 14, 1993], a **composite metallized propellant** using ADN (instead of AP),  $\text{AlH}_3$  (instead of Al), and nitrate ester binder offers the highest  $I_s$  among all of the currently viable solid rocket propellants.

Objective identify a viable High Specific Impulse and Green Propellant for European launchers and space exploration motors (within the framework of two successive European Projects, called HISP and GRAIL, both coordinated by the Swedish FOI).

By properly **combining** three inorganic oxidizers all based on the ammonium cation ( $\text{NH}_4^+$ ), the innovative ADN with the two well-known salts AN and AP, a wide range of interesting applications beyond the current limitations appear feasible.

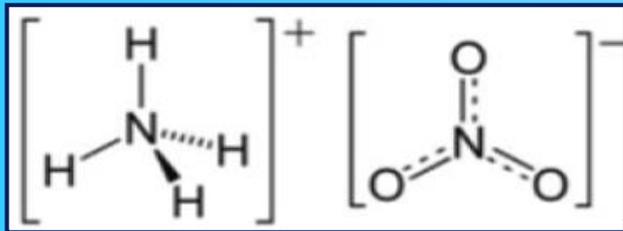

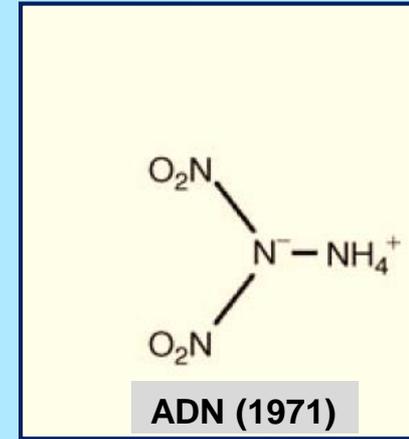

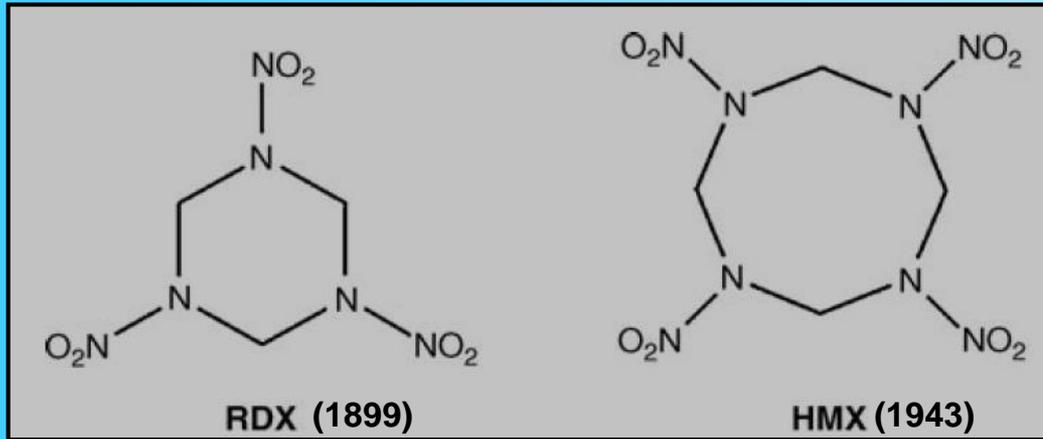

SPLab of PoliMi is in charge of the high-energy metallic fuel (formulation + characterization).

# ADN PECULIARITIES

AN and AP are both well-known and have been used at all levels for several decades, whereas ADN is a relatively new product.

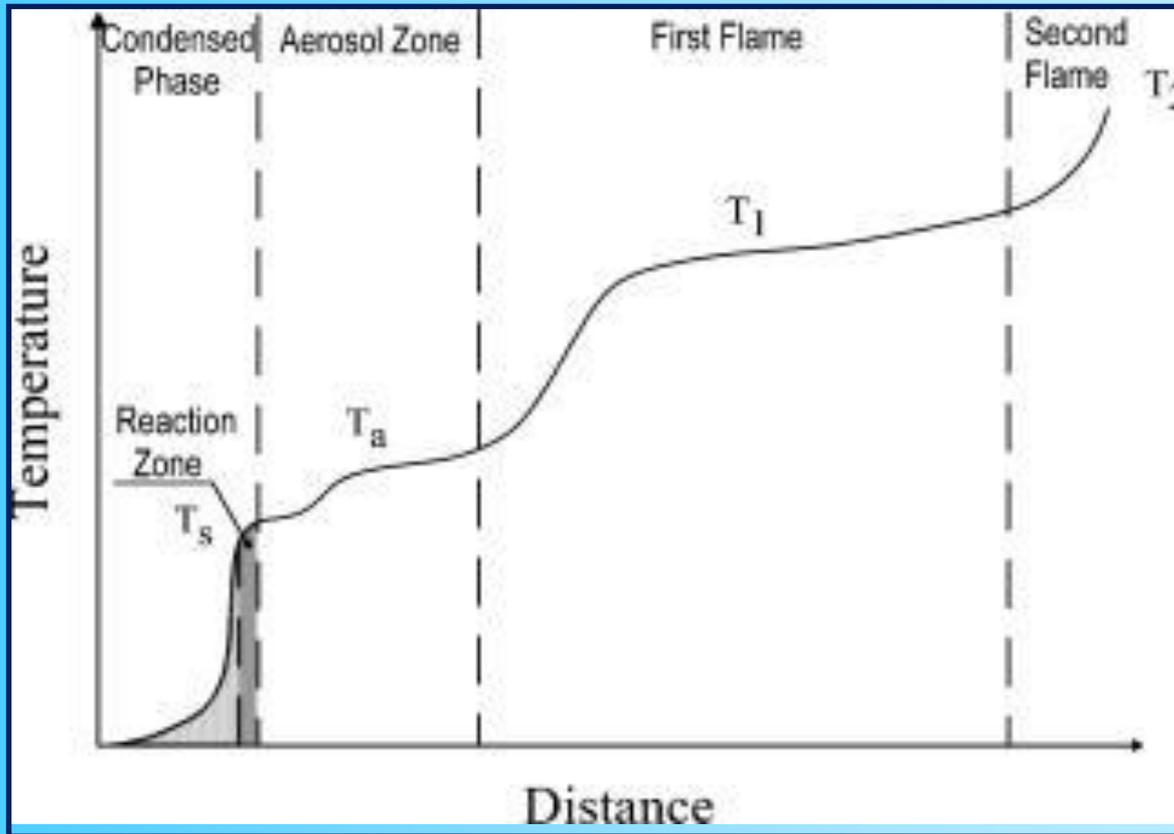

- first synthesized at the Zelinsky Institute of Organic Chemistry in Moscow, Russia, 1971 (and much later at SRI, USA, 1988).
- Unconfirmed: ADN-based SRM are in **operational use** by Russian ICBM.
- main advantages of ADN as an oxidizer are “superior” performance ( $I_s$ ), good ballistic properties (high burning rates and possible low pressure sensitivity), low signature, and total environmental respect.
- however, **strong sensitivity** to humidity (like AN) and initial temperature (like AN) as well as low melting (92-94 °C or 365–367 K) and decomposition (starting at 135 °C or 408 K) temperatures make its field use problematic.
- **prilling** technique required to overcome difficulties with needle shape.
- ADN also possesses a number of unique properties, such as high condensed phase heat capacity of 0.59 cal/g/K, low surface temperatures, and a low PDL around 2 atm.
- ADN burning as a monopropellant is a quite **complex** process whose characterization is hindered by a conspicuous **data scattering** reported by many investigators.

# Ballistic Properties: steady $r_b$

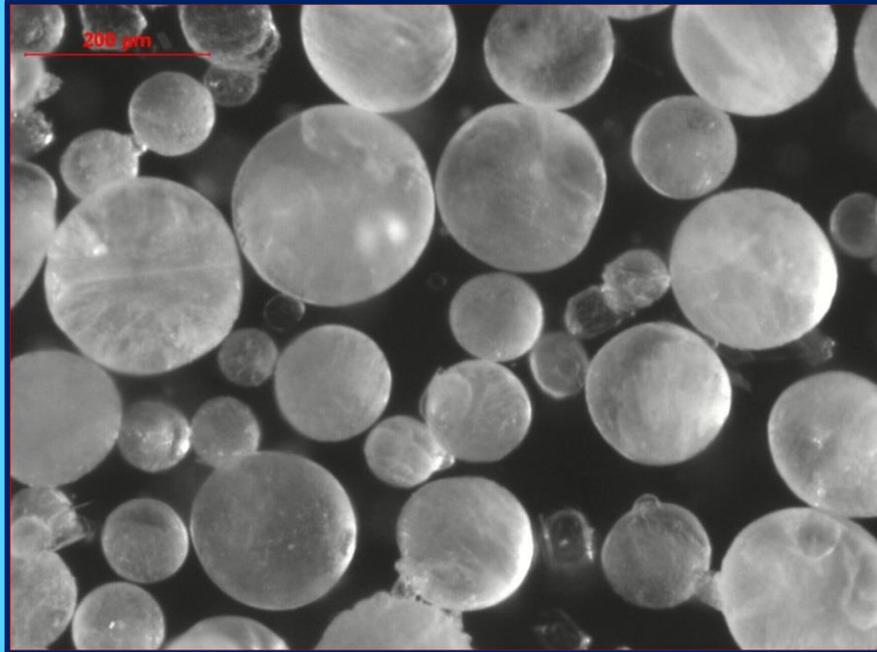

Steady burning rate vs. pressure for a wide range of solid propellant formulations tested at SPLab compared to ADN data from literature.

# Flame Structure ADN

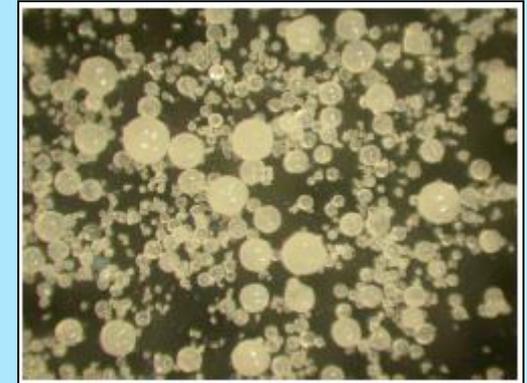

Sketch of ADN multistep flame structure [Sinditskii et al.<sup>21</sup>]. Burning appears flameless below 1 bar, condensed-phase controlled up to 10 bar, unstable up to 100 bar, and collapses to one, luminous, gas-phase controlled zone above 100 bar.

# ADN Prilling at ICT and FOI

Micrograph (reflected light) of prilled ADN; mean particle size 208 μm (ICT).

Spray prilled ADN (FOI).

ADN-Prilling process used at ICT is an **emulsion crystallization** technology developed at the end of the 1990s (European patent). Achievable particle size range could be enlarged down to 35 μm and up to 320 μm. Typical ADN-prill sizes for reproducible kg-scale productions are: 50 μm fine and 200 μm coarse.

ADN-Prilling process used at FOI is based on crystallization after **molten ADN spray** through a nozzle.

## $\mu$ Al powders (Avio $\leftrightarrow$ UK)

- typically in the range **15 to 45**  $\mu\text{m}$ , density  $2.7 \text{ g cm}^{-3}$ , active Al  $>99\%$ , spherical shape;
- BET surface  $\approx 0.10 \text{ m}^2/\text{g}$  and  $T_{\text{ign}} > 1000 \text{ K}$ .

## nAl powders (STK by EEW)

- typically in the range **50 to 100** nm (at most 150 nm), density  $\approx 2.5 \text{ g cm}^{-3}$ , active Al  $\approx 70-90\%$ ; ESD hazard;
- BET surface 7 to  $16 \text{ m}^2/\text{g}$  (clustering and increase of propellant viscosity) and  $T_{\text{ign}} \cong 770$  to  $950 \text{ K}$ .

## chem-actAl powders (FOI)

- based on Valimet H3  $\mu$ Al ( $2.73 \text{ g cm}^{-3}$  density and  $3 \mu\text{m}$  size), but details undisclosed;
- BET surface 2 to  $3 \text{ m}^2/\text{g}$  and  $T_{\text{ign}} \cong 860$  to  $905 \text{ K}$ .

## mec-actAl powders (SPLab)

- based on Avio  $\mu$ Al from Alpocho, but details undisclosed;

## amAl powders (ESA)

- details undisclosed.

**More undefined ingredients  
may be tested provided by  
international manufacturers**

...

## Stabilized $\text{AlH}_3$ (TNO, U. Poitiers)

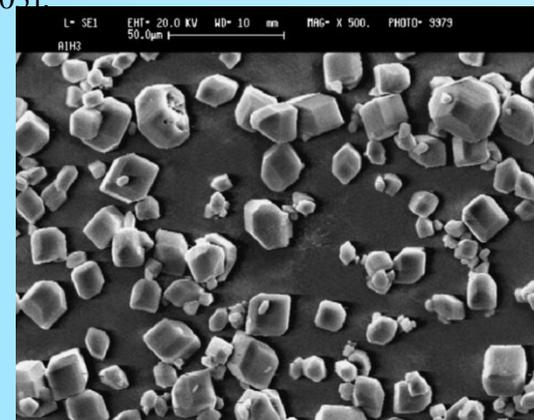

- big crystals **1-20**  $\mu\text{m}$  size of irregular structure, low density ( $1.477 \text{ g cm}^{-3}$ ),  $88.2\%$  ( $89.9\%$  theoretical) active Al;
- decomposition temperature of  $179.7 \text{ }^\circ\text{C}$ , about  $20 \text{ }^\circ\text{C}$  higher than usual [ICT 2003];
- outstanding storage stability (superior to common  $\mu$ Al powders);
- marginal handling stability, poor under ESD,  $T_{\text{ign}} = 614 \text{ K}$ .

## Other Metal Hydrides (Chemetal, commercial)

- $\text{LiAlH}_4$  ( $T_{\text{ign}} = 398 \text{ K}$ , density =  $0.917 \text{ g cm}^{-3}$ );
- $\text{Li}_3\text{AlH}_6$  ( $T_{\text{ign}} = 451 \text{ K}$ , density =  $1.130 \text{ g cm}^{-3}$ );
- $\text{MgH}_2$  ( $T_{\text{ign}} = 835 \text{ K}$ , density =  $1.450 \text{ g cm}^{-3}$ ); ...

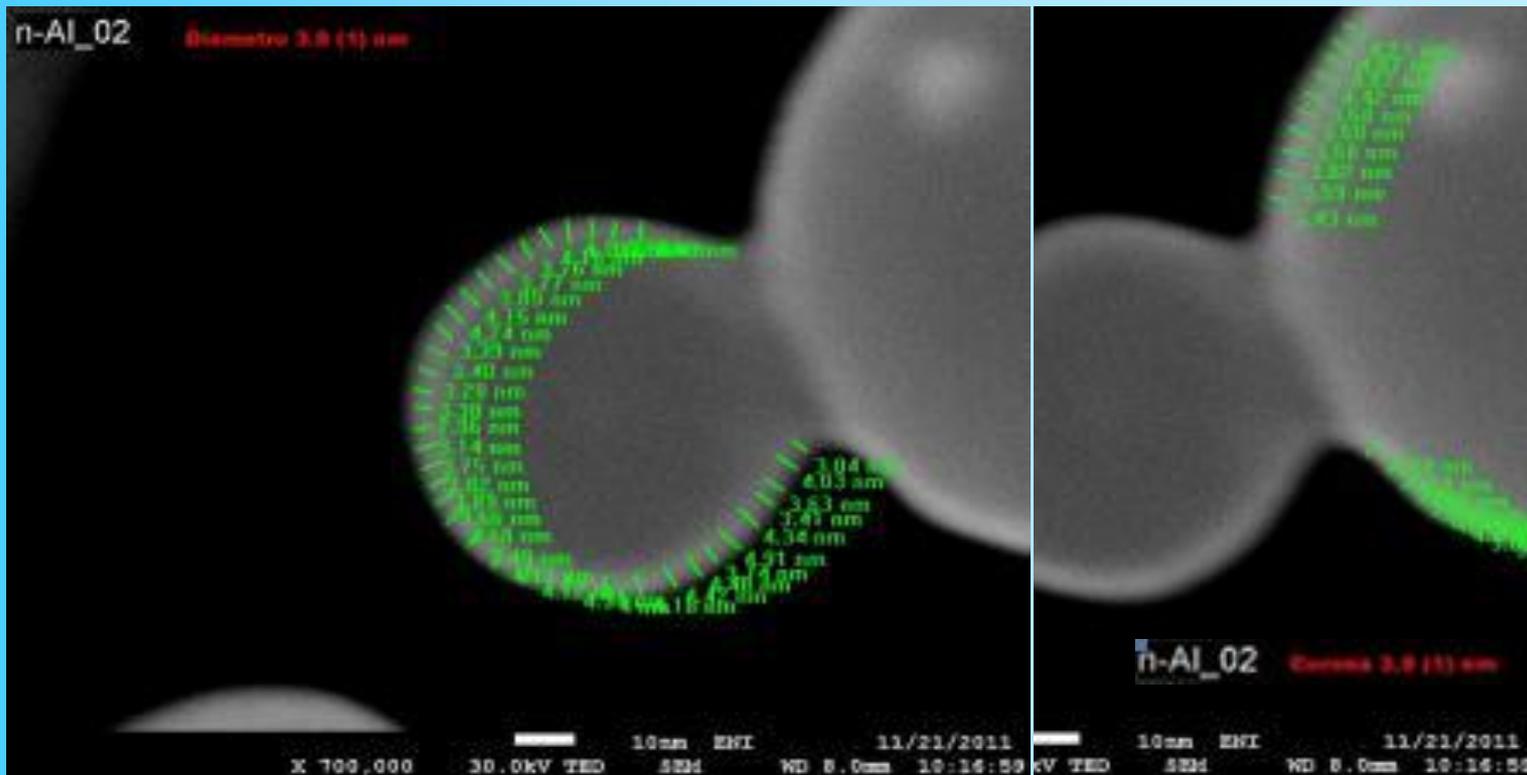

## $\text{Mg}_x\text{B}_y$ composite metal (MACH-I)

- particle size essentially in the range 1-20  $\mu\text{m}$ ;
- B purity 90 or 95%;
- Mg coating ranging from 10 to 60%;
- ignition temperature  $T_{\text{ign}}$  reduced to 835-950 K.

 (c) porous structure after decomposition at 400 °C (ICT testing).

# Metallic Fuels: $\mu\text{Al}$ vs. $\text{nAl}$

DeLuca 41

The well-known technology of nano metal powders successful in many fields overall not yet ready for rocket propulsion (good for increase of  $r_b$  not  $I_s$ , effective for dynamic burning) for a series of drawbacks including:

- clustering of particles [1, Ch. 27];
- decreased active metal content ( $I_s$  reduction)  $\rightarrow$  not less than 85%  $\rightarrow$  avoid too small particle size;
- dependence on passivation technique;
- ESD, impact, and friction hazards;
- possible catalytic effects on propellant curing;
- increased viscosity of the propellant;
- ageing of particles;
- and increased cost.

Compensating effects of decreased 2P flow losses (delivered  $I_s$  increase) vs. decreased active metal content ( $I_s$  reduction), when using  $\text{nAl}$  as high-energy fuel.

# Accumulation & Aggregation & Agglomeration

## *AP/HTPB/Al*

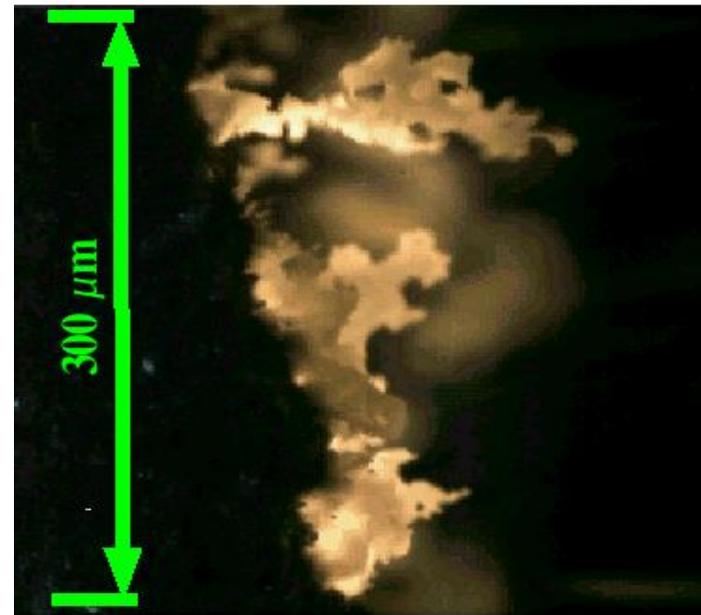

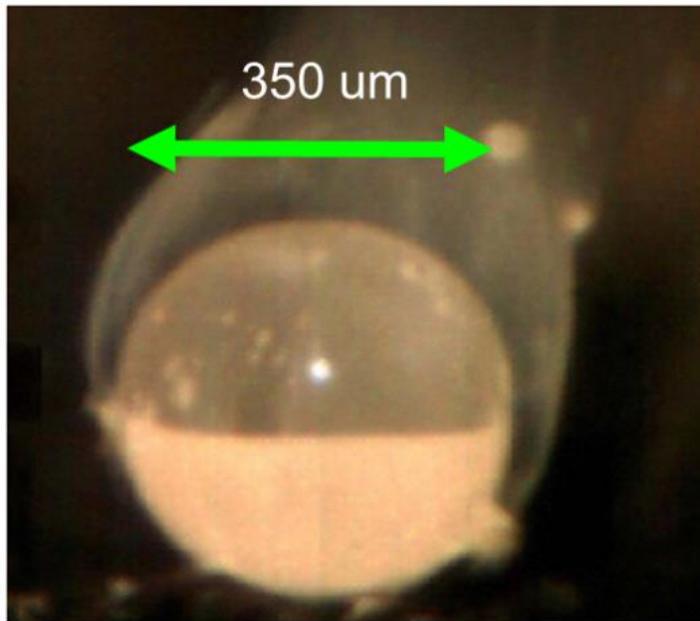

Transition from surface accumulate (skeleton layer) first to aggregates (partial oxidation) and then to agglomerates (burning spheres) for  $\mu\text{Al}$  particle clusters. [Video SPLab: AP/HTPB/ $\mu\text{Al}$  industrial propellant microstructure].

# Agglomeration vs. Aggregation

- Accumulate (or skeleton layer) is the material stacking up on the burning surface; its nature is tightly related to tested energetic material.
- **Aggregation = partial (or final) oxidation step** characterized by CCP of irregular shape, often seen as intermediate between accumulates and agglomerates. It implies **high** temperatures.
- **Agglomeration = final oxidation step** characterized by spherical drops of liquid metal in combustion, starting from aggregates (seen as precursors of agglomerates). It **implies and actually need high** temperatures for inflammation.
- Agglomeration always implies a loss of the **initial particle individuality**, while aggregation may keep some reminiscence of it.
- **Clustering = assembling of particles before combustion**, during manufacture and storage, typical of nAl powders. It implies **ambient** temperatures.
- Cohesion (or adhesion) = “a portion of a substance cleaving together in a thick nondescript mass”.
- Coagulation = “viscous lump of a portion of liquid” (from Merriam-Webster Dictionary).

# Agglomeration vs. Aggregation

## *Al size effect in AP/HTPB matrix*

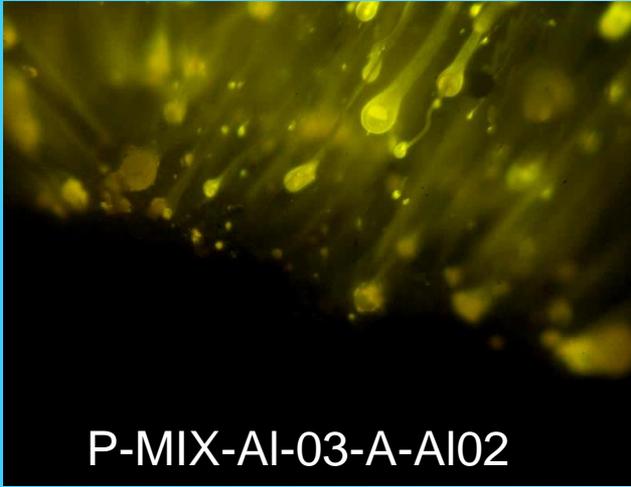

**Left** - Magnified view of a single spherical agglomerate of  $\mu\text{Al}$  in combustion *above* propellant surface following inflammation of aggregates (filaments or filigrees) *at* the propellant surface, with loss of the initial particle individuality.

**Right** – Oxidized metal flakes emerging from the burning surface of a  $0.15\ \mu\text{m}$   $\text{nAl}$  propellant tested at 10 bar, with flakes replicating the 3D  $\text{nAl}$  distribution in the propellant matrix.

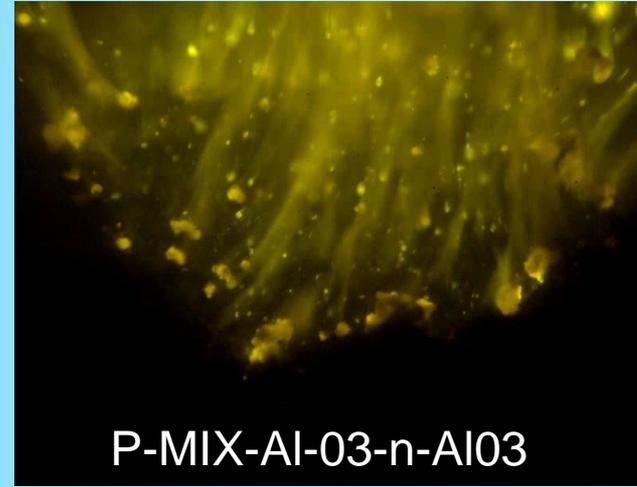

→  $\text{nAl}$  particles imply larger SSA and reactivity, higher  $r_b$ , effects slope ?, less agglomeration, unchanged ideal  $I_s$ , increased delivered  $I_s$ .

Current state of the art of solid propellants is based on AP/HTPB/ $\mu$ Al.

AP is an outstanding solid oxidizer (a “miracle of nature”), but

- Ozone layer depletion
- Acid rains
- Thyroid gland interference

New solid oxidizer?

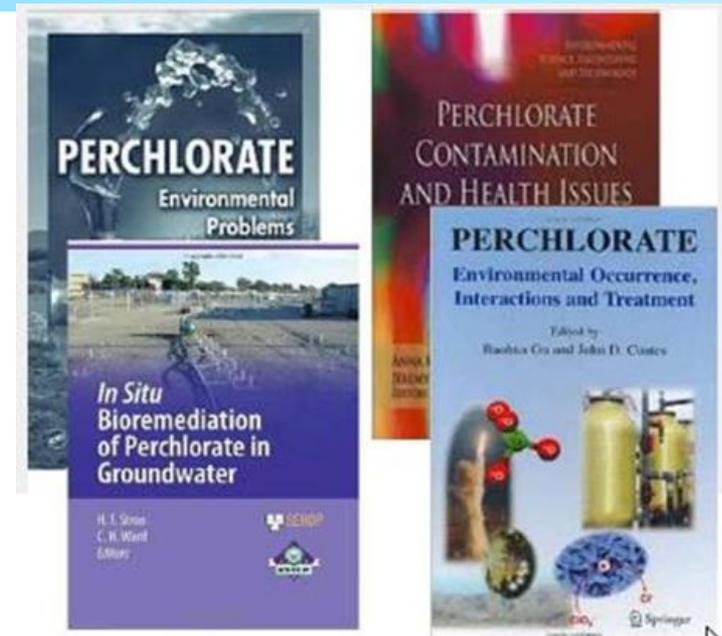

Replace AP with a mixture of the two green oxidizers:

- Ammonium Dinitramide (ADN)
- Ammonium Nitrate (AN)

GRAIL (Green Advanced High Energy Propellants for Launchers) project was funded by the European Union’s Horizon 2020 research and innovation program, as continuation of HISP (High performance solid propellants for In-Space Propulsion) project already funded in the framework of the FP7 program.

HISP duration was of 3 years (2011-2013), [www.hisp-fp7.eu](http://www.hisp-fp7.eu)

GRAIL duration again of 3 years (2015-2017), [www.grail-h2020.eu](http://www.grail-h2020.eu)

# RECOMMENDATIONS FUTURE WORK

DeLuca 49

- For the near future, formulations including **dual-oxidizers** based on ADN, such as (ADN+AN) or (ADN+AP), in conjunction with a **dual-metallic** fuel based on  $\mu\text{Al}$ , such as ( $\mu\text{Al}+\text{nAl}$ ) or ( $\mu\text{Al}+\text{AlH}_3$ ), bound by a suitable active or inert binder, are expected to advance the state-of-the-art of solid rocket propellants.
- However, the quite peculiar properties of ADN require a careful design and implementation of the propellant formulation. Most investigations so far accomplished did not fully exploit the unusual dependence of ADN ballistic properties on particle size. Appropriate burning rate modifiers or coolants may be needed to fully control the propellant **internal ballistic properties**.
- At this time, in view of the already available experimental results described, the mixture **(ADN+AP) seems easier** to master than (ADN+AN).
- Overall, when dealing with ADN, it is the **binder system** still demanding a decisive effort to manufacture well-behaved formulations; other critical areas are the implementation of a suitable **phase-stabilizer** for AN (PSAN obtained by  $\text{KNO}_3$  was compatible with ADN but not if obtained by  $\text{NiO}$  [30]) and **bonding agent** for the propellant (HX-880, also known as BHEGA, is compatible with AP but not with ADN [1, Ch. 32]).
- At any rate, the mechanical and hazard properties of the resulting formulations have to be closely monitored and possibly improved. Target is **class 1.3** for hazard rating.

- Hybrid rocket engines are an attractive “new” option (low TRL) for a range of applications including minilaunchers (CNES Perseus), boosters (ASI), upper stage propulsion (PF7 Orphée), lander systems (PF7 Spartan), private human space access (IAA), active space debris removal (IAA), in-space navigation ...
- Application of HRE based on  $H_2O_2$  + rubber to cruise stages of light-weight launch vehicles, boosters and interorbital towing vehicles, as well as to launching boosters of LV with cruise oxygen LRE of various classes is economically justified; few years of good stay in space expected (KeRC).
  - Higher  $I_s$  than SP and monopropellant LP
  - Simpler system and lower development cost than bipropellant LP
  - High throttleability
  - High versatility
  - On-off capability
  - Safety
  - Commandable cut once desired  $\Delta V$  is reached (ADR)
  - Low regression rates suitable to avoid excessive accelerations (ADR)
- Enhance combustion efficiency and regression rate.
  - Low regression rate overcome by fuel formulation and multiport grain
  - High O/F mitigate negative effects of low regression rates
  - Excessive engine L/D ratio overcome by technological advances (see LM)
  - Ad-hoc geometries of injector/grain (single swirl → 3X, double coaxial swirl → 6X, vortex flow pancake → reduced L/D, CAMUI → ...) can sensibly help ...

# Regression HTPB in GOX: Pressure Effect

DeLuca 55

- Operating conditions: 4-16 bar and 210 Nlpm pure oxygen flow rate
- Complete set of ensemble average curves of  $r_f$  vs.  $G_{ox}$
- Linear regression rate essentially independent of pressure (at most, slightly decreasing)
- Confirmed also for HRE in the range of  $p_c = 24$  to 44 bar [Risha 2003]
- Constant power law regression rate (Marxman) **not** valid, it should be seen as an approximation.

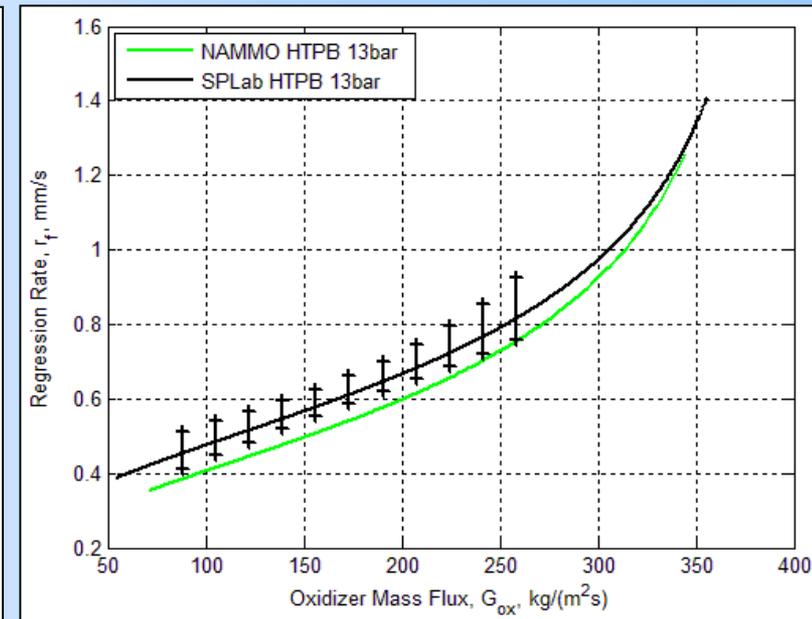

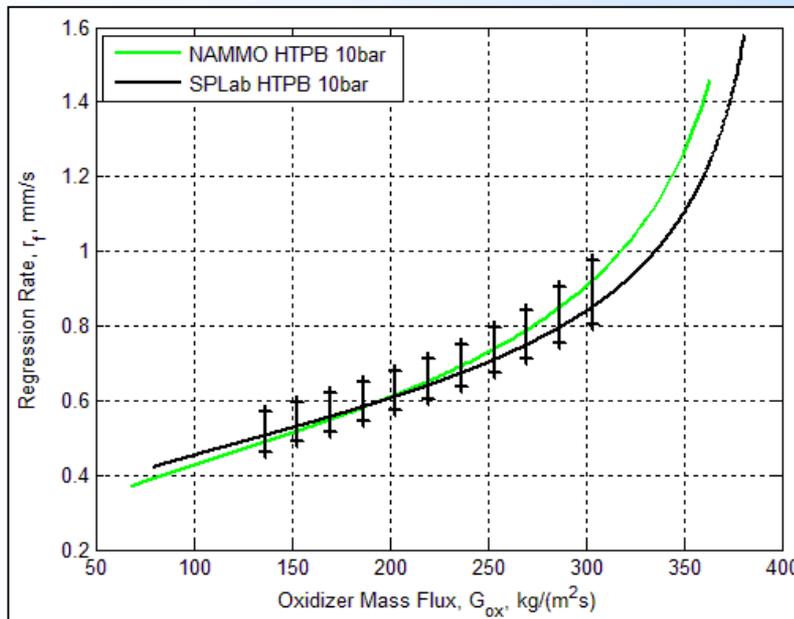

**Journal of Propulsion and Power, 2012, under press**  
*Solid Fuel Regression Rate Modeling for Hybrid Rockets*

# Regression HTPB in GOX: Industrial Check

DeLuca 56

Comparing SPLab and industrial (NAMMO) samples of pure HTPB

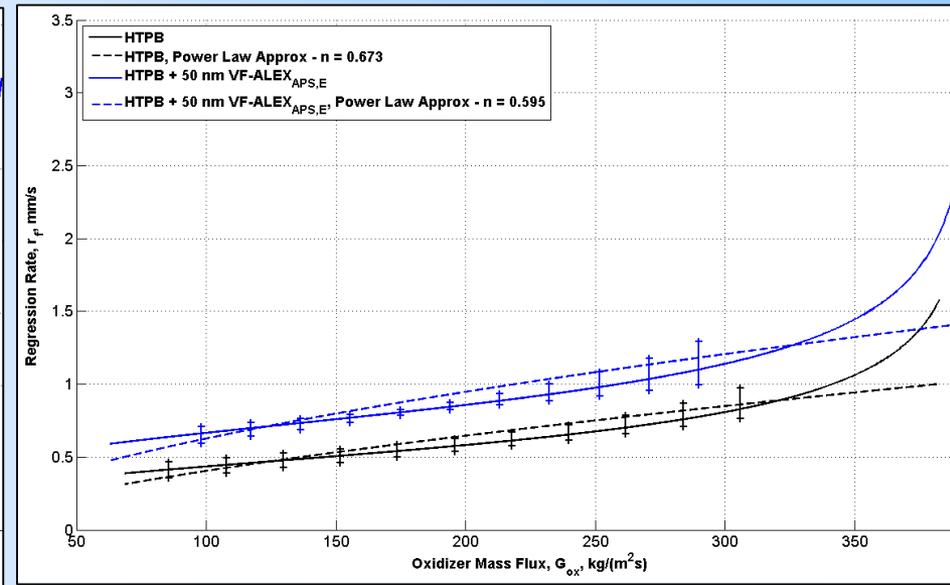

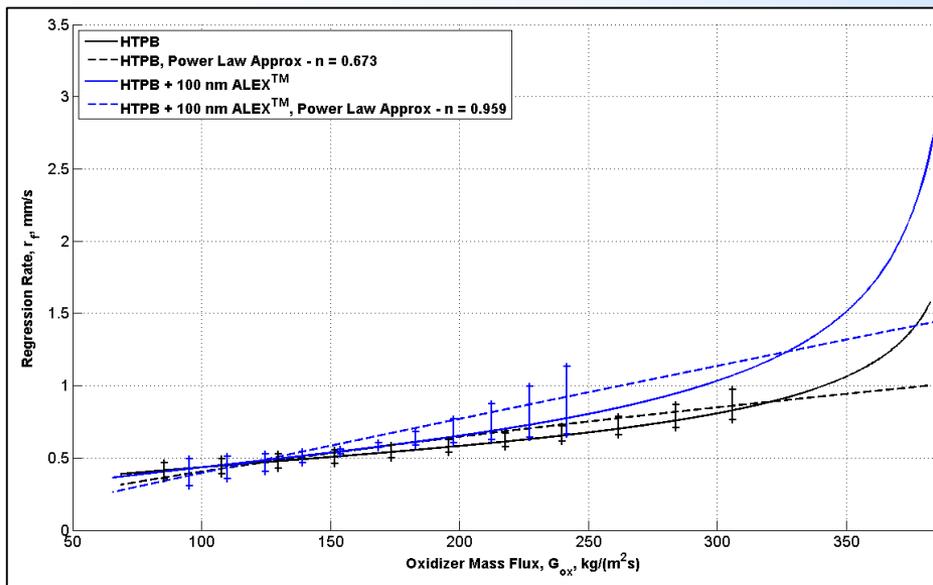

Comparing instantaneous regression rates of pure HTPB burning under GOX at 10 bar (left) and 13 bar (right) for SPLab and industrial formulations, under 210 Nlpm pure O<sub>2</sub> flow rate.

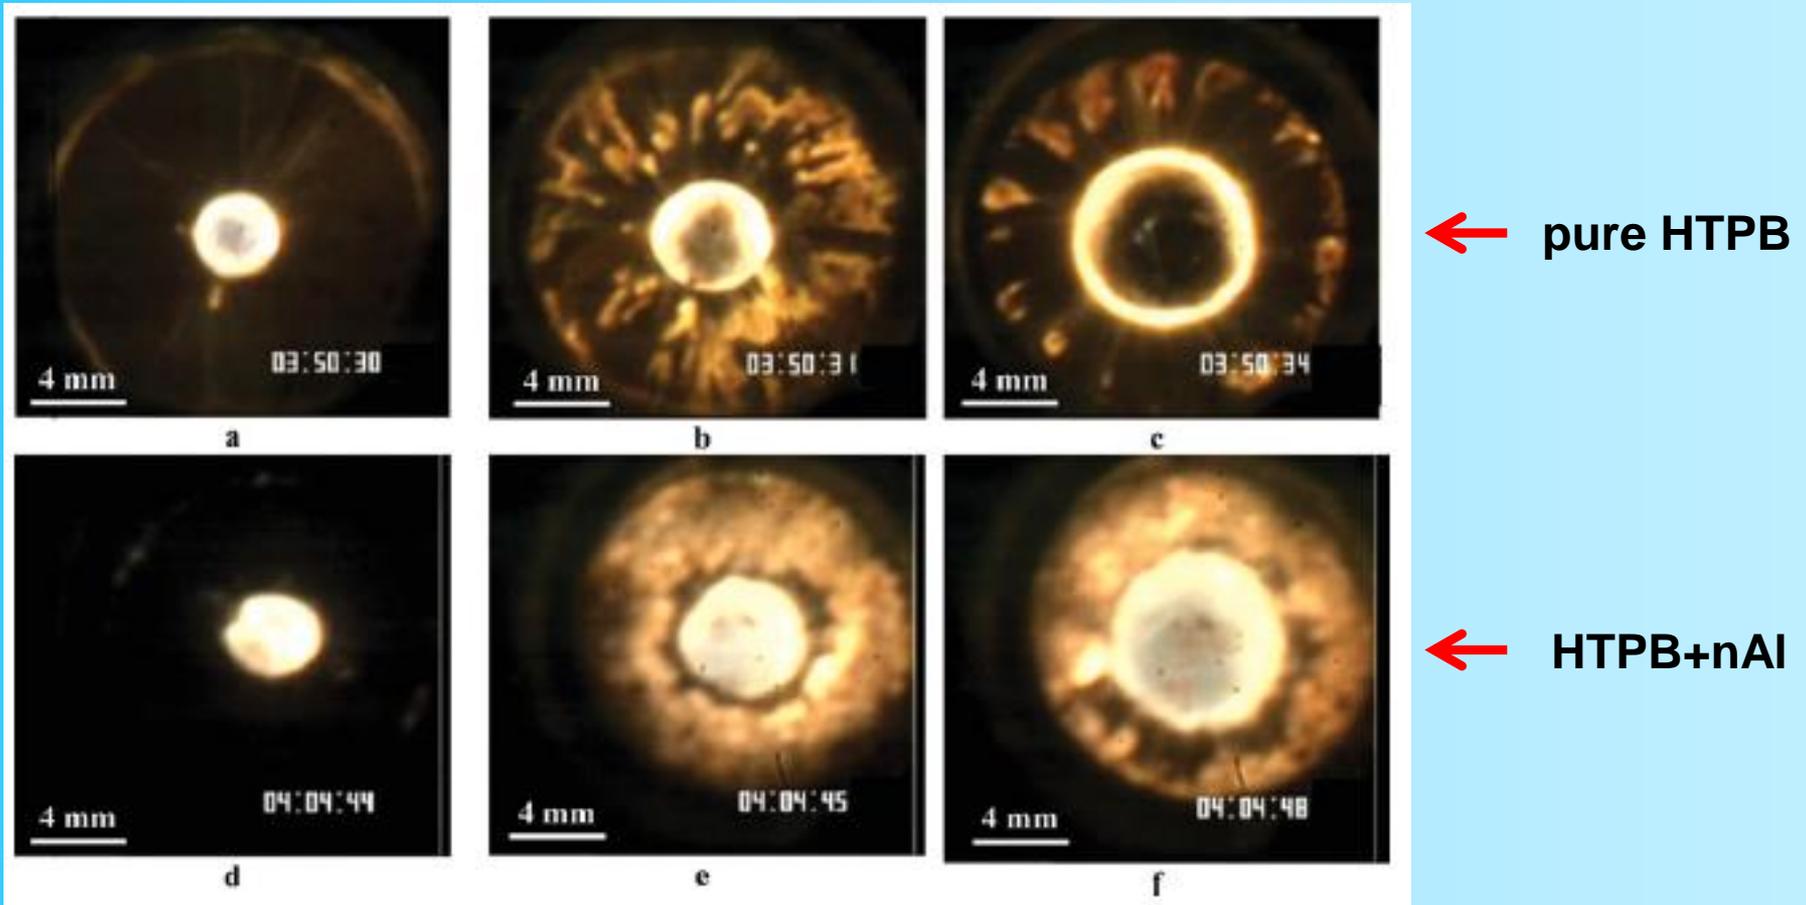

# Regression HTPB + nAl in GOX

- DeLuca 57
- Operating conditions: 10 bar and 210 Nlpm pure oxygen flow rate
  - Complete set of ensemble averages curves for a wide range of loaded HTPB
  - For all tests, under high oxidizer mass flux, initial regression rates are in excess wrt power-law approximation (constant power law **not** valid)

Ensemble instantaneous regression rate of loaded HTPB + 100 nm ALEX (left) and + 50 nm VF-ALEX<sub>APS,E</sub> (right) each compared to pure HTPB.

Only fluoroelastomer coatings yield nearly **constant** increase of regression rate.

Sample frames of HTPB burning tests under GOX: pure HTPB (a:  $t_{ign}$ ; b:  $t_{ign} + 1$  s; c:  $t_{ign} + 4$  s) and nAl-loaded HTPB (d:  $t_{ign}$ ; e:  $t_{ign} + 1$  s; f:  $t_{ign} + 4$  s).

# Summary Hybrid Propulsion

## AUGMENTING SOLID FUELS

While  $\mu\text{Al}$  does not contribute to specific impulse, hydrides ( $\text{AlH}_3$ ,  $\text{LiAlH}_4$ ,  $\text{MgH}_2$ ) and other metals ( $\text{nAl}$  or  $\text{Mg}_x\text{B}_y$ ) promote regression rate, mitigate nozzle erosion and soot formation, and may increase density.

- $\text{AlH}_3$  ( $1.476 \text{ g/cm}^3$ ) and  $\text{LiAlH}_4$  ( $0.917 \text{ g/cm}^3$ ) outstanding  $I_s$  increase, but  $\text{LiAlH}_4$  suffers low density
- $\text{B}_{10}\text{H}_{14}$  ( $0.94 \text{ g/cm}^3$ ) outstanding  $I_s$  and regression rate (in 92%  $\text{H}_2\text{O}_2$ ) increase, modest density
- F-coated  $\text{nAl}$  ( $\rho \cong 2.520 \text{ g/cm}^3$ ) helps to reduce  $I_s$  losses, increases density and regression rates
- $\text{Mg}_x\text{B}_y$  ( $1.450 \text{ g/cm}^3$ ) can sensibly increase regression rate, but no  $I_s$  increase
- Note limited compatibility of hydrides with HTPB

## BURNING SOLID FUELS

Large-scale operations need advanced fuels combining good handling, mechanical, and ballistic properties:

- instantaneous regression does **not** obey standard constant power law even under ss
- deeper understanding of flame structure for soot formation
- VFP pancake design promising for ADR
